How to add Secure Boot to DSC and FDF

Based on original variable driver in MdeModulePkg, variable driver in SecurityPkg provides authenticated variable service in UEFI 2.3.1 spec. Runtime crypto library, OpenSSL* library and variable driver are required to enable this feature.

1. Ensure OpensslLib* library instance is defined in [LibraryClasses] section of the platform DSC file:
 - IntrinsicLib|CryptoPkg/Library/IntrinsicLib/IntrinsicLib.inf
 - OpensslLib|CryptoPkg/Library/OpensslLib/OpensslLib.inf
2. Ensure BaseCryptLib library instances are defined in the platform DSC file:
 - For PEI driver: BaseCryptLib|CryptoPkg/Library/BaseCryptLib/PeiCryptLib.inf

OS BOOTS, NOW WHAT?

UEFI and Management Mode (formerly known as SMM)

Platform Initialization (PI) Specification Introduces Management Mode (MM)**

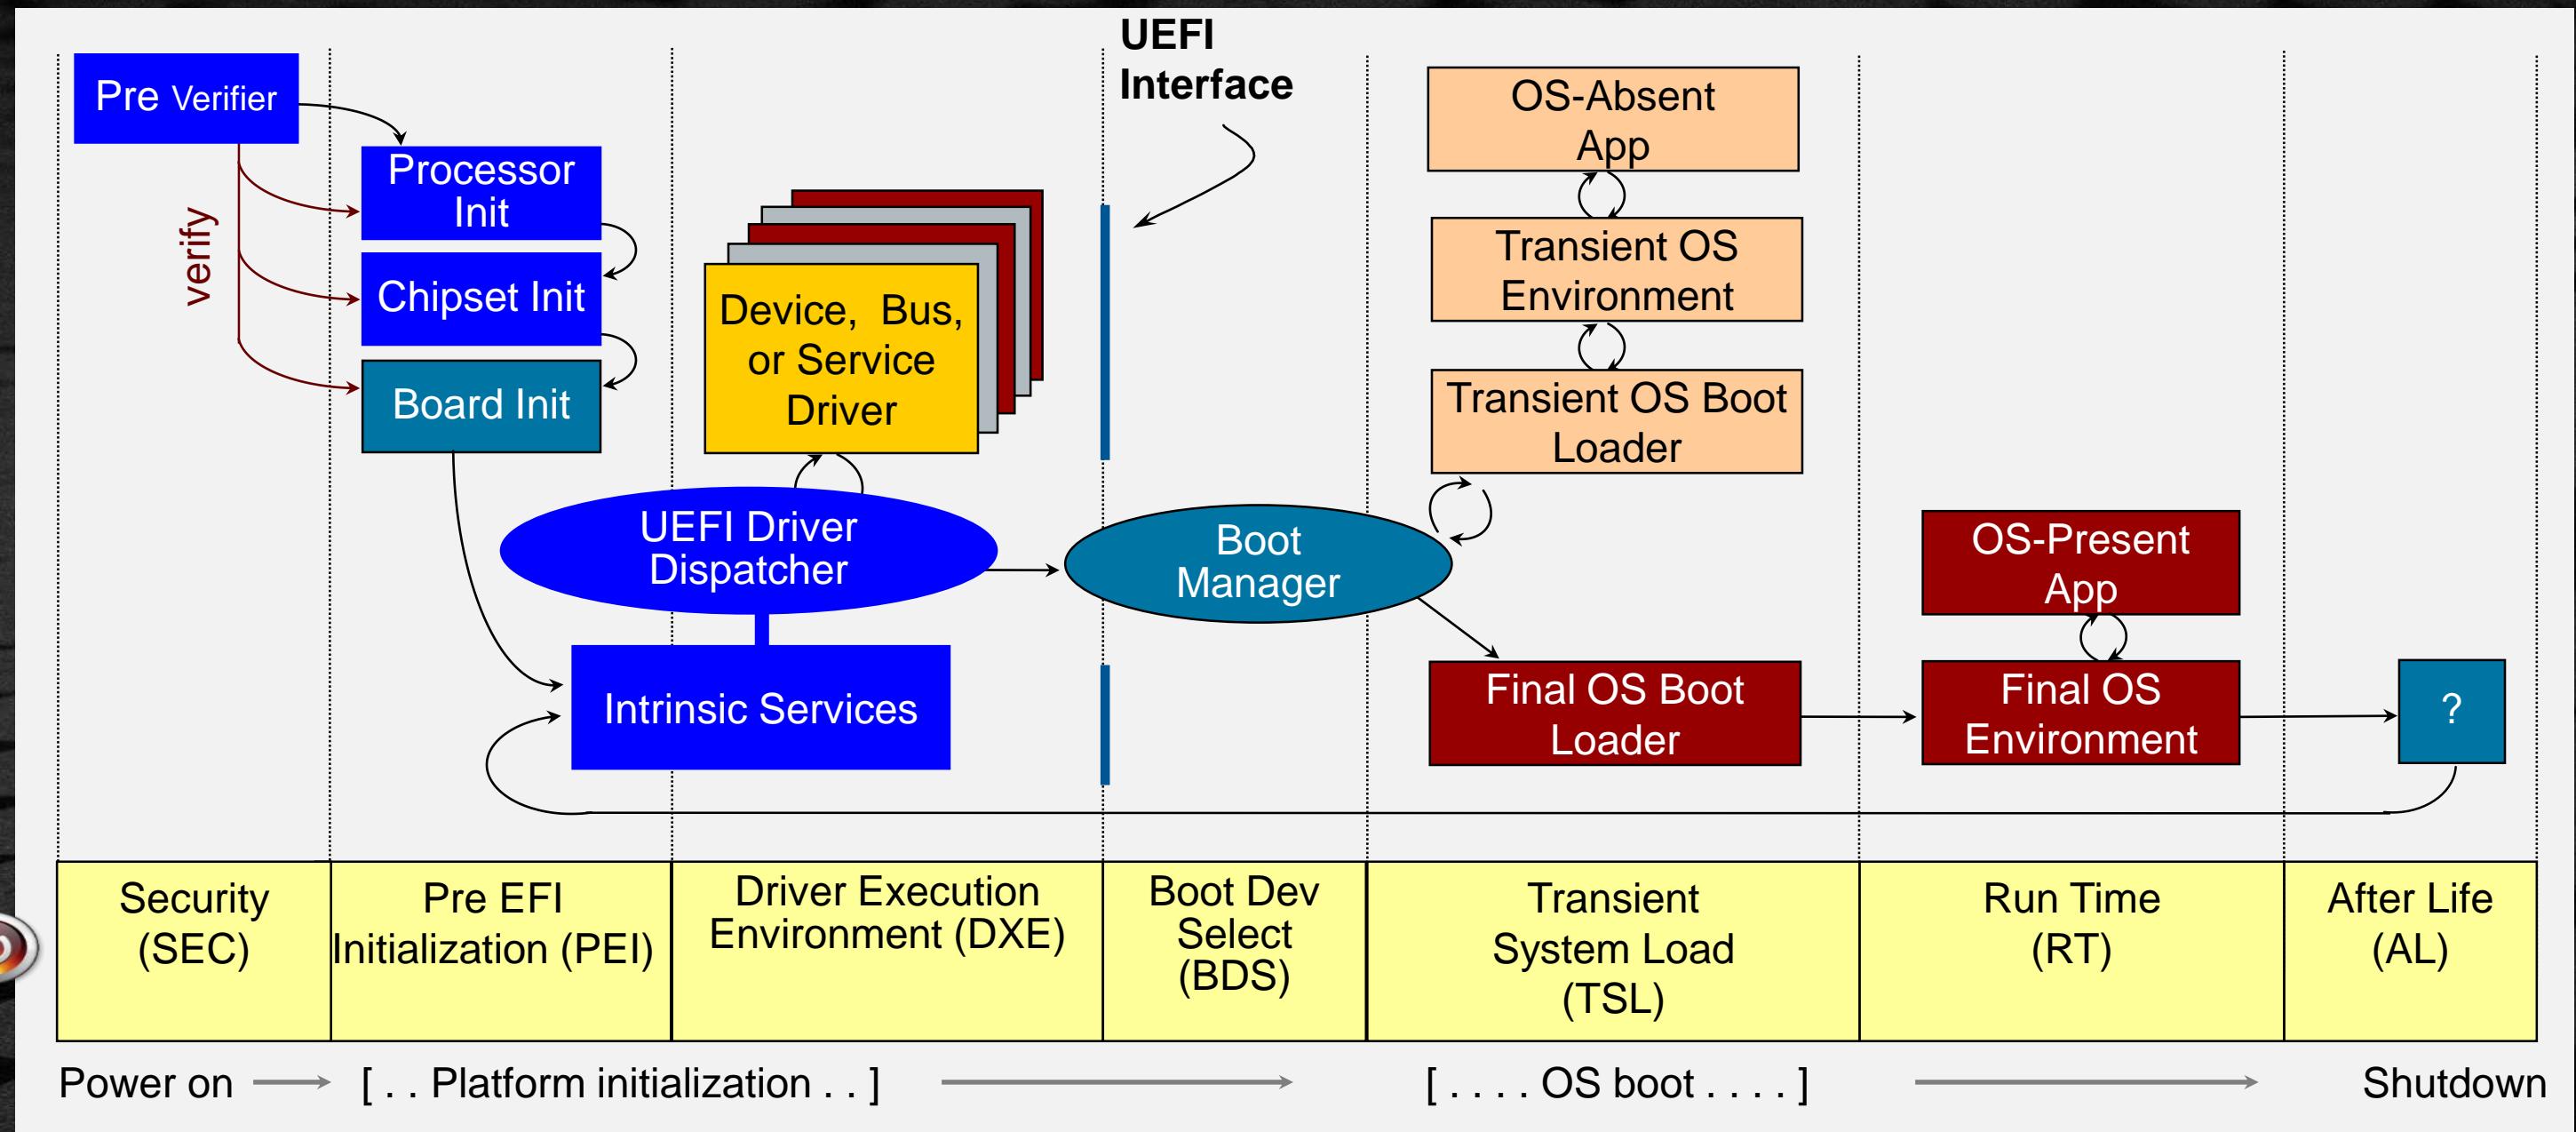

UEFI PI-standard for creating a protected execution environment using hardware resources

- Dedicated, protected memory space, entry point and hardware resources, such as timers and interrupt controllers
- Implemented using SMM (Intel® Architecture) or TrustZone(Arm)
- Highest-privilege operating mode (Ring 0) with greatest access to system memory and hardware resources

Software Management Mode Interrupts (Software MMIs)

- Management Mode Interrupts generated by software synchronously are called Software MMIs
 - Generated using I/O resources or CPU instructions
- Used to provide firmware services to the
 - OS (ACPI, TPM)
 - OS drivers (device handoff, CPU management)
 - UEFI runtime support (variables, capsule, etc.)
 - BIOS vendor applications (flash utilities, setup access)
 - OEM/ODM applications

Why are Software MMI Vulnerabilities Dangerous?

Because . . .

Software MMIs can be asked to perform:

- Privileged operations: Flash BIOS, flash EC, write to MMIO, write to MMRAM, etc.
- Overwrite OS code/data
- Copy protected OS data to another unprotected location
- Copy protected firmware data to another unprotected location
- Overwrite BIOS code/data

UEFI Platform Firmware Assumptions

- Memory protected by the OS cannot be snooped while in use by the OS application or OS driver
 - No protection from MM, VMs or hardware snooping
- Flash protected by hardware cannot be modified outside of MM after the end of DXE
 - Not worried about snooping since no secrets are stored in BIOS
 - Not worried about flash-altering hardware attacks
- Software MMIs cause CPUs to enter SMM in SMRAM at a fixed location
- MMRAM cannot be altered from outside SMM

Key Points for More Secure Software MMI Handlers

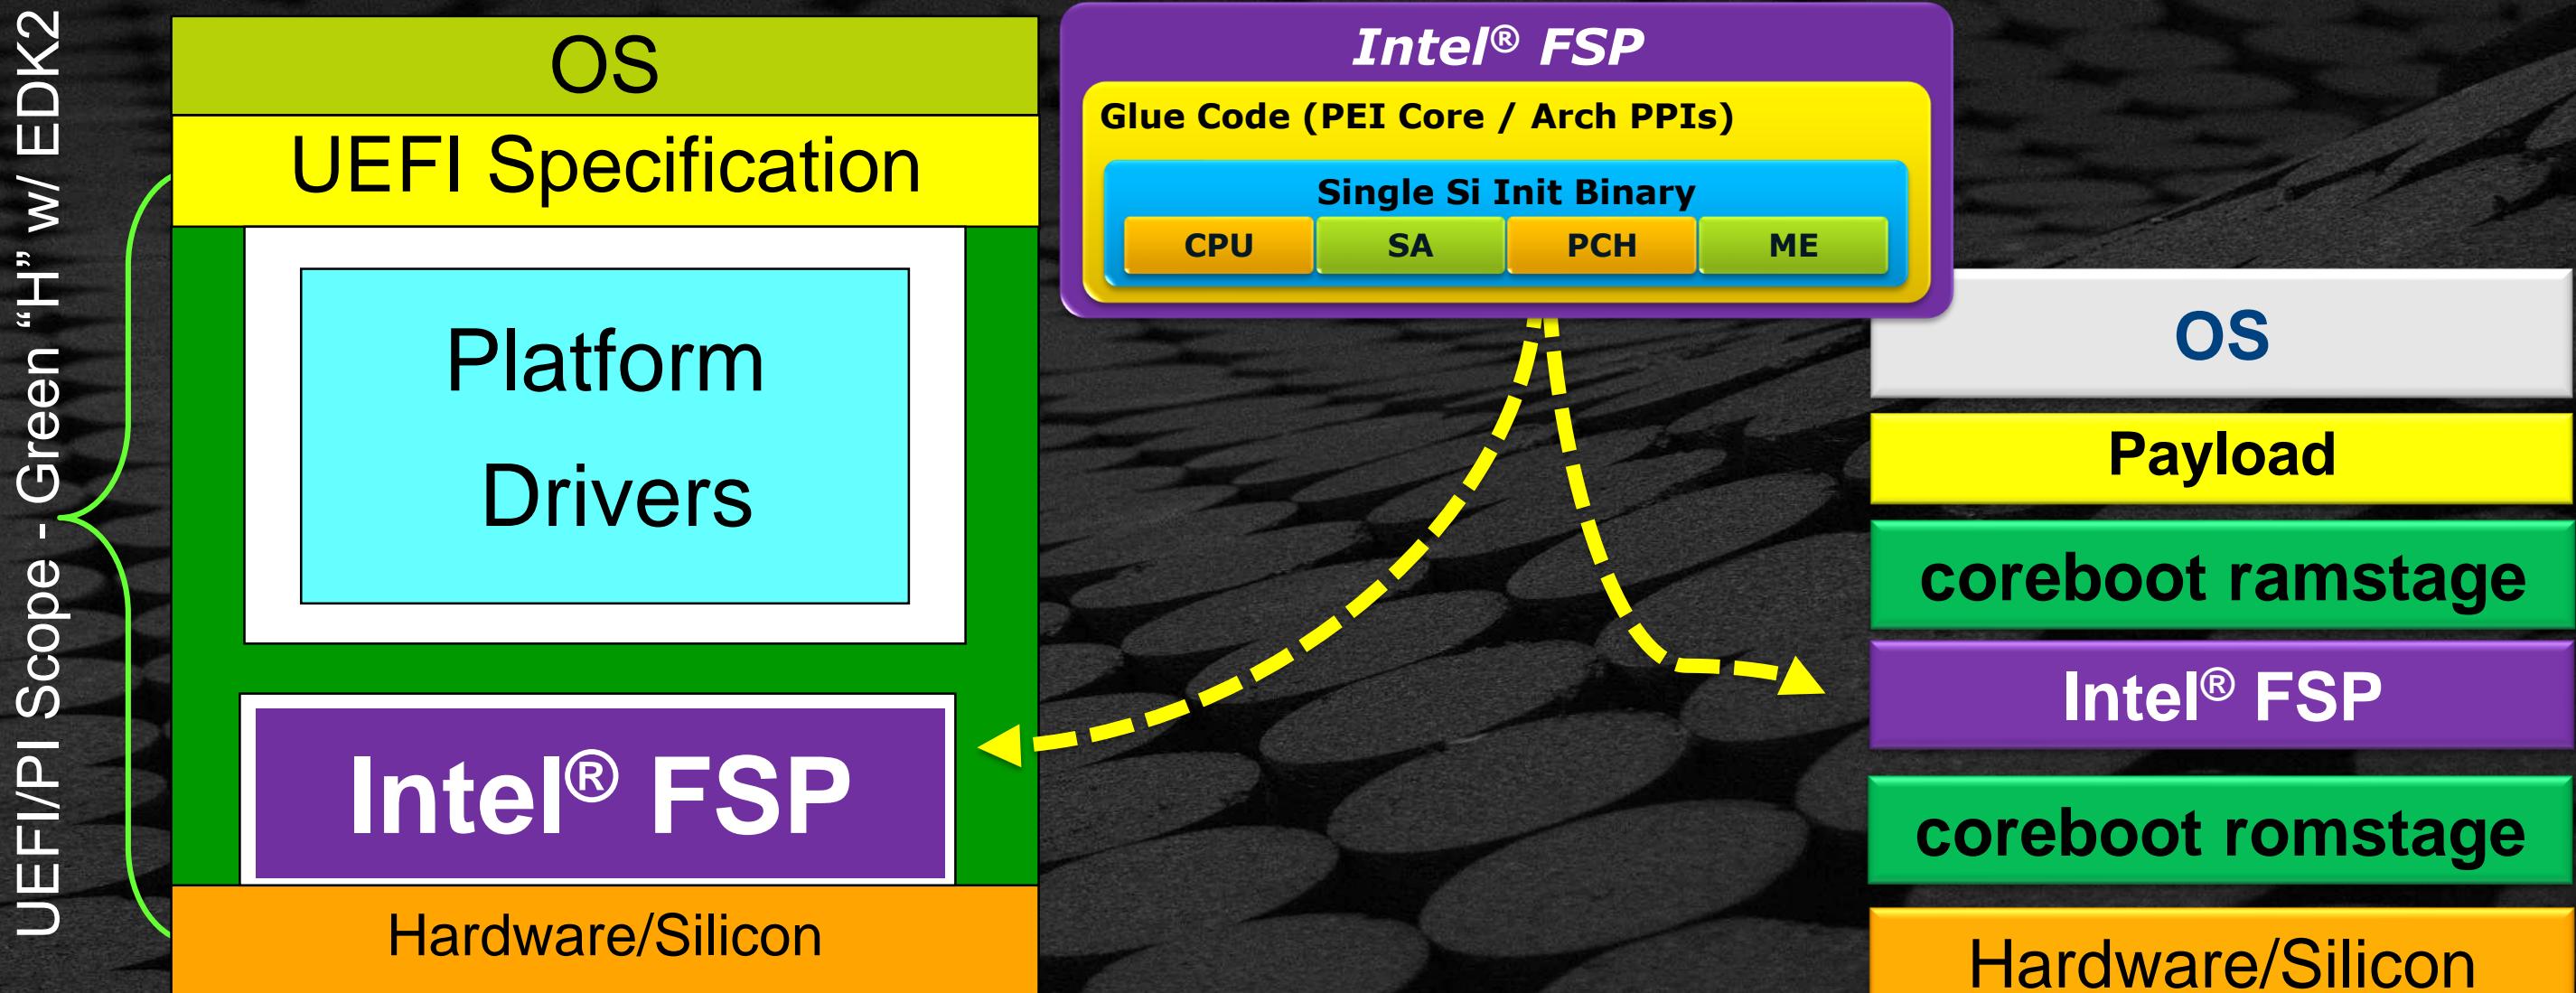

- Allocate The Buffer In PEI/DXE
- Never Trust That Pointers Point To The Buffer
- Prohibit Input/Output Buffer Overlap
- Don't Trust Structure Sizes
- Verify Variable-Length Data

COREBOOT

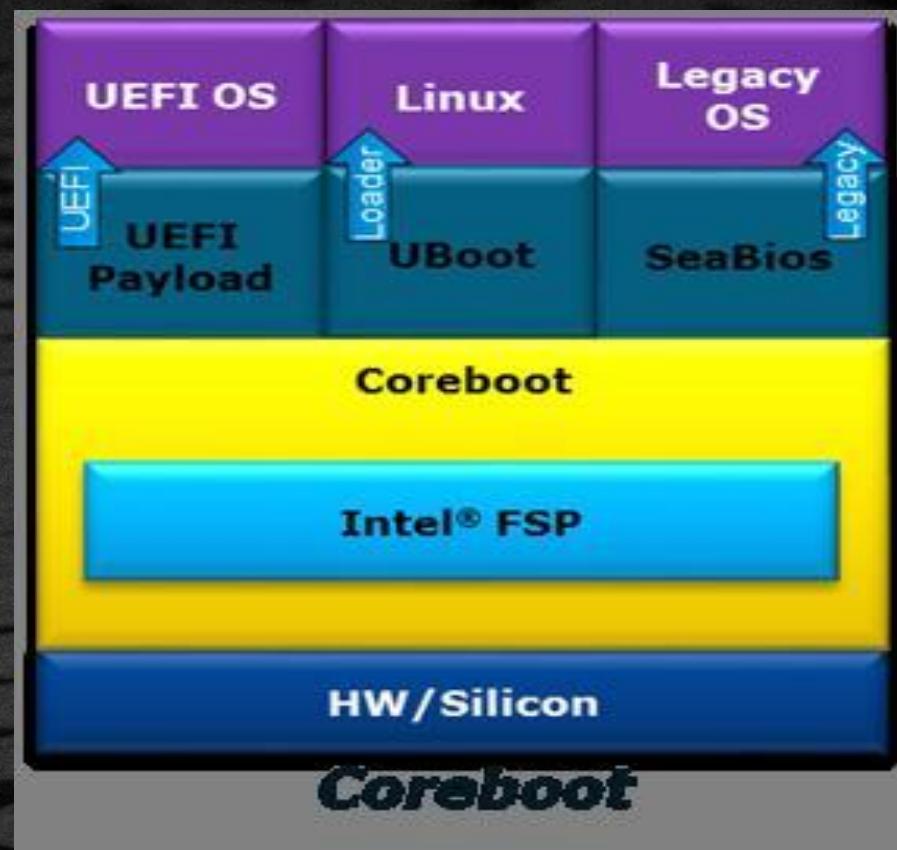

How does coreboot work with UEFI

Intel® FSP "Produced" to "Consuming" Intel® Architecture Firmware

Intel FSP is independent of the bootloader solutions

Coreboot Payload

Coreboot in itself is "only" minimal code for initializing hardware. It does not have the media drivers nor does it provide services required by an OS. After the initialization, it jumps to a payload which can provide services required to load and boot an OS.

UEFI payload provides UEFI services on top of coreboot that allows UEFI OS boot.

Consumers: EDK II firmware and coreboot

Functionality	coreboot	UEFI / PI
The reset vector and pre cache-as-ram setup	bootblock	Security Phase (SEC)

UEFI Secure Boot

- Deficiency: Boot path malware targets
- UEFI and Secure Boot harden the boot process
- Firmware/software in the boot process must be signed by a trusted Certificate Authority (CA)
- Firmware image is hardware-protected
- 3rd party drivers signed using CA-holding trusted keys
- Trusted signing key's database factory-initialized and OS-updated

WHY??? SECURE Boot WITH UEFI

Without

Possible corrupted or destroyed data

- BootKit virus – MBR Rootkits
- Network boot attacks e.g. PXESPOILT
- Code Injection Attacks

With

- Data integrity
- Trusted boot to OS
- Trusted drivers
- Trusted Applications
